Movie Recommendation System

A content-based film finder built around personal preferences

PROJECT	TECHNOLOGY	METHOD
CodSoft AI Internship Task	HTML, CSS, JavaScript	Content-based filtering

Project overview

For this project, I built a movie discovery app called Frame. Users select genres, moods, and a runtime preference, then receive a ranked list of matching movies. The dashboard also lets users mark movies as seen and optionally hide them.

Recommendation method

I used content-based filtering. Each movie in the sample collection has genre and mood tags. The app compares those tags with the user's selected preferences, assigning 3 points for each matching genre and 2 points for each matching mood. It sorts movies by their total score, then applies the chosen runtime and seen filters.

Why a movie was recommended

Each result card displays the preferences that matched, so the user can see why that film appeared. If no preferences are selected, the app shows a mixed selection. If filters leave no matches, it explains how to broaden the choices.

What I learned

This project helped me understand how item descriptions can be used to rank recommendations. I practiced scoring and sorting records, filtering a collection based on user input, and explaining a recommendation in the interface. The demo uses a fixed movie list and does not learn from other users.

How to run

Open **index.html** in a modern web browser. Choose genres, moods, and a runtime, then select **Find my next film**. No installation or server is needed.
