Rule-Based Chatbot

A friendly browser chatbot using text patterns and predefined replies

PROJECT	TECHNOLOGY	METHOD
CodSoft AI Internship Task	HTML, CSS, JavaScript	Rules + regular expressions

Project overview

For this project, I built a browser-based chatbot called Milo. It responds to messages using predefined rules, so it is easy to run and the response logic is visible in the source code. The chat has a message box, example prompts, timestamps, and a clear-chat button.

How Milo understands a message

The code first normalizes the user's text by converting it to lowercase, trimming extra spaces, and removing most punctuation. It then checks the message against regular-expression patterns in order. For example, words such as "hello", "hi", and "hey" match the greeting rule. The first matching rule determines the reply.

Conversation flow

Milo has rules for greetings, its name, time and date questions, jokes, study tips, help, thanks, and goodbyes. The time and date replies use the browser's local clock. When a message does not match a rule, Milo gives a fallback reply with suggestions. The rules are checked in order so specific patterns can be handled before broader ones.

What I learned

This project gave me practice with basic natural-language processing ideas such as text normalization and pattern matching. I also learned how to organize responses as rules and connect them to a chat interface. This is a rule-based demonstration: Milo does not learn from conversations or call an online AI service.

How to run

Open **index.html** in a modern web browser. Type a message or choose one of the example prompts, then press Enter or select the send arrow. No installation or server is needed.
